

1.2W Audio Power Amplifier with Active-Low Standby Mode

- Operating from $V_{CC} = 2.2V$ to $5.5V$
- 1.2W Output power @ $V_{CC}=5V$, THD=1%, $f=1kHz$, with 8Ω Load
- Ultra-low consumption in standby mode (10nA)
- 62dB PSRR @ 217Hz in grounded mode
- Near-zero POP & CLICK
- Ultra-low distortion (0.1%)
- Unity gain stable
- Available in a 9-bump Flip-Chip, MiniSO8 and DFN8 packages

Description

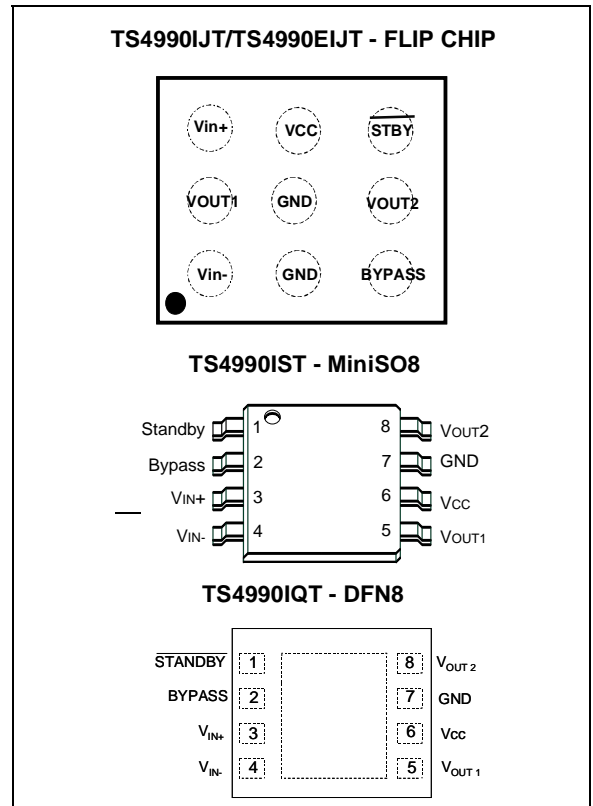

The TS4990 has been designed for demanding audio applications such as mobile phones and to minimize the number of external components.

This Audio Power Amplifier is capable of delivering 1.2W of continuous RMS Output Power into an 8Ω load @ 5V.

An externally-controlled standby mode reduces the supply current to less than 10nA. It also includes internal thermal shutdown protection.

The unity-gain stable amplifier can be configured by external gain setting resistors.

Pin Connections (top view)

Applications

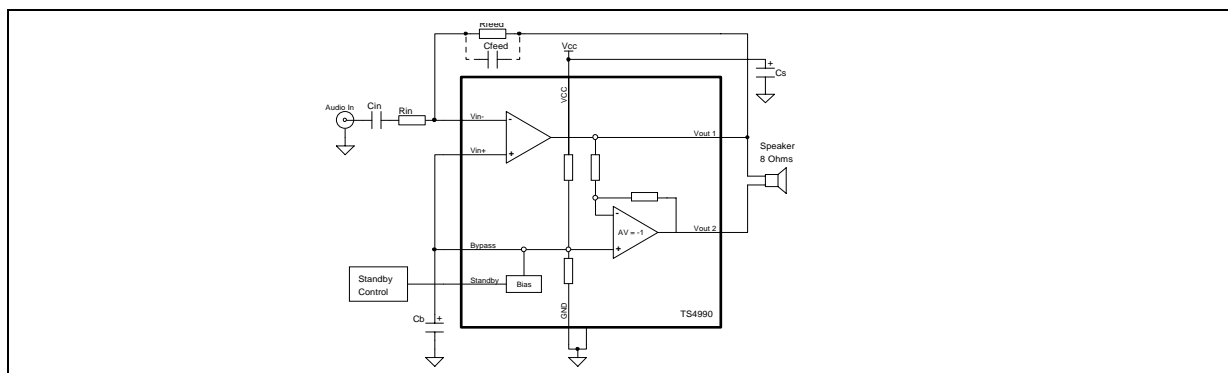

- Mobile phones (cellular / cordless)
- PDAs
- Laptop / notebook computers
- Portable audio devices

Table 6:Components description

Components	Functional Description
R_{in}	Inverting input resistor which sets the closed loop gain in conjunction with R_{feed} . This resistor also forms a high pass filter with C_{in} ($f_c = 1 / (2 \times \pi \times R_{in} \times C_{in})$)
C_{in}	Input coupling capacitor which blocks the DC voltage at the amplifier input terminal.
R_{feed}	Feed back resistor which sets the closed loop gain in conjunction with R_{in} .
C_s	Supply Bypass capacitor which provides power supply filtering.
C_b	Bypass pin capacitor which provides half supply filtering.
C_{feed}	Low pass filter capacitor allowing to cut the high frequency (low pass filter cut-off frequency $1 / (2 \times \pi \times R_{feed} \times C_{feed})$)
A_v	Closed loop gain in BTL configuration = $2 \times (R_{feed} / R_{in})$
Exposed Pad	DFN8 Exposed pad is electrically connected to pin7. See page 24 for more information.

3 Application Information

3.1 BTL configuration principle

The TS4990 is a monolithic power amplifier with a BTL output type. BTL (Bridge Tied Load) means that each end of the load is connected to two single-ended output amplifiers. Thus, we have:

$$\text{Single-ended output 1} = V_{out1} = V_{out} \text{ (V)}$$

$$\text{Single ended output 2} = V_{out2} = -V_{out} \text{ (V)}$$

$$\text{and } V_{out1} - V_{out2} = 2V_{out} \text{ (V)}$$

The output power is:

$$P_{out} = \frac{(2V_{outRMS})^2}{R_L}$$

For the same power supply voltage, the output power in BTL configuration is four times higher than the output power in single ended configuration.

3.2 Gain In typical application schematic

The typical application schematic is shown in page 1.

In the flat region (no C_{in} effect), the output voltage of the first stage is (in Volts):

$$V_{out1} = (-V_{in}) \frac{R_{feed}}{R_{in}}$$

For the second stage: $V_{out2} = -V_{out1}$ (V)

The differential output voltage is (in Volts):

$$V_{out2} - V_{out1} = 2V_{in} \frac{R_{feed}}{R_{in}}$$

The differential gain named gain (G_v) for more convenient usage is:

$$G_v = \frac{V_{out2} - V_{out1}}{V_{in}} = 2 \frac{R_{feed}}{R_{in}}$$

V_{out2} is in phase with V_{in} and V_{out1} is phased 180° with V_{in} . This means that the positive terminal of the loudspeaker should be connected to V_{out2} and the negative to V_{out1} .

3.3 Low and high frequency response

In the low frequency region, C_{in} starts to have an effect. C_{in} forms with R_{in} a high-pass filter with a -3dB cut-off frequency. F_{CL} is in Hz.

$$F_{CL} = \frac{1}{2\pi R_{in} C_{in}}$$

In the high frequency region, you can limit the bandwidth by adding a capacitor (C_{feed}) in parallel with R_{feed} . It forms a low-pass filter with a -3dB cut-off frequency. F_{CH} is in Hz.

$$F_{CH} = \frac{1}{2\pi R_{feed} C_{feed}}$$

The following graph shows an example of C_{in} and C_{feed} influence.

Figure 60: Frequency response gain vs C_{in} , & C_{feed}

3.4 Power dissipation and efficiency

Hypotheses:

- Load voltage and current are sinusoidal (V_{out} and I_{out})
- Supply voltage is a pure DC source (V_{cc})

Regarding the load we have:

$$V_{out} = V_{PEAK} \sin\omega t \text{ (V)}$$

and

$$I_{\text{out}} = \frac{V_{\text{out}}}{R_L} \text{ (A)}$$

and

$$P_{\text{out}} = \frac{V_{\text{PEAK}}^2}{2R_L} \text{ (W)}$$

Therefore, the average current delivered by the supply voltage is:

$$I_{\text{CC AVG}} = 2 \frac{V_{\text{PEAK}}}{\pi R_L} \text{ (A)}$$

The power delivered by the supply voltage is:

$$P_{\text{supply}} = V_{\text{CC}} I_{\text{CC AVG}} \text{ (W)}$$

Then, the **power dissipated by each amplifier** is

$$P_{\text{diss}} = P_{\text{supply}} - P_{\text{out}} \text{ (W)}$$

$$P_{\text{diss}} = \frac{2\sqrt{2}V_{\text{CC}}}{\pi\sqrt{R_L}} \sqrt{P_{\text{out}}} - P_{\text{out}}$$

and the maximum value is obtained when:

$$\frac{\partial P_{\text{diss}}}{\partial P_{\text{out}}} = 0$$

and its value is:

$$P_{\text{diss max}} = \frac{2V_{\text{CC}}^2}{\pi^2 R_L} \text{ (W)}$$

Note: This maximum value is only dependent on power supply voltage and load values.

The **efficiency** is the ratio between the output power and the power supply

$$\eta = \frac{P_{\text{out}}}{P_{\text{supply}}} = \frac{\pi V_{\text{PEAK}}}{4V_{\text{CC}}}$$

The maximum theoretical value is reached when $V_{\text{peak}} = V_{\text{CC}}$, so

$$\frac{\pi}{4} = 78.5\%$$

3.5 Decoupling of the circuit

Two capacitors are needed to correctly bypass the TS4990. A power supply bypass capacitor C_S and a bias voltage bypass capacitor C_B .

C_S has particular influence on the THD+N in the high frequency region (above 7kHz) and an indirect influence on power supply disturbances. With a value for C_S of 1 μ F, you can expect similar THD+N performances to those shown in the datasheet.

In the high frequency region, if C_S is lower than 1 μ F, it increases THD+N and disturbances on the power supply rail are less filtered.

On the other hand, if C_S is higher than 1 μ F, those disturbances on the power supply rail are more filtered.

C_B has an influence on THD+N at lower frequencies, but its function is critical to the final result of PSRR (with input grounded and in the lower frequency region).

If C_B is lower than 1 μ F, THD+N increases at lower frequencies and PSRR worsens.

If C_B is higher than 1 μ F, the benefit on THD+N at lower frequencies is small, but the benefit to PSRR is substantial.

Note that C_{in} has a non-negligible effect on PSRR at lower frequencies. The lower the value of C_{in} , the higher the PSRR.

3.6 Wake-up time: T_{WU}

When the standby is released to put the device ON, the bypass capacitor C_B will not be charged immediately. As C_B is directly linked to the bias of the amplifier, the bias will not work properly until the C_B voltage is correct. The time to reach this voltage is called wake-up time or T_{WU} and specified in electrical characteristics table with $C_B=1\mu$ F.

If C_B has a value other than 1 μ F, please refer to the graph in Figure 60 to establish the wake-up time value.

Figure 61: Typical wake-up time vs. C_b

Due to process tolerances, the maximum value of wake-up time could be established by the graph in Figure 61:

Figure 62: Maximum wake-up time vs. C_b

Note: Bypass capacitor C_b as also a tolerance of typically +/-20%. To calculate the wake-up time with this tolerance, refer to the previous graph (considering for example for $C_b=1\mu\text{F}$ in the range of $0.8\mu\text{F}\leq C_b\leq 1.2\mu\text{F}$).

3.7 Shutdown time

When the standby command is set, the time required to put the two output stages in high impedance and the internal circuitry in shutdown mode is a few microseconds.

Note: In shutdown mode, Bypass pin and Vin- pin are short-circuited to ground by internal switches. This allows a quick discharge of C_b and C_{in} capacitors.

3.8 Pop performance

Pop performance is intimately linked with the size of the input capacitor C_{in} and the bias voltage bypass capacitor C_b .

The size of C_{in} is dependent on the lower cut-off frequency and PSRR values requested. The size of C_b is dependent on THD+N and PSRR values requested at lower frequencies.

Moreover, C_b determines the speed with which the amplifier turns ON. In order to reach near zero pop and click, the equivalent input constant time,

$$\tau_{in} = (R_{in} + 2k\Omega) \times C_{in} \text{ (s) with } R_{in} \geq 5k\Omega$$

must not reach the τ_{in} maximum value as indicated in the graph below.

Figure 63: τ_{in} max. versus bypass capacitor

By following previous rules, the TS4990 can reach near zero pop and click even with high gains such as 20 dB.

Example:

With $R_{in} = 22 \text{ k}\Omega$ and a 20 Hz, -3 db low cut-off frequency, $C_{in}=361 \text{ nF}$. So, $C_{in}=390 \text{ nF}$ with standard value which gives a lower cut-off frequency equal to 18.5 Hz. In this case, $(R_{in} + 2 \text{ k}\Omega) \times C_{in} = 9.36 \text{ ms}$. When referring to the previous graph, if $C_b = 1 \mu\text{F}$ and $V_{cc} = 5 \text{ V}$, we read 20 ms max. This value is twice as high as our current value, thus we can state that pop and click will be reduced to its lowest value.

Minimizing both C_{in} and the gain benefits both the pop phenomena, and the cost and size of the application.

3.9 Application: differential inputs btl power amplifier

The schematic in Figure 63 shows how to design the TS4990 to work in a differential input mode.

The gain of the amplifier is:

$$G_{VDIFF} = 2 \frac{R_2}{R_1}$$

In order to reach the optimal performance of the differential function, R_1 and R_2 should be matched at 1% max.

Figure 64: Differential input amplifier configuration

The input capacitor C_{IN} could be calculated by the

following formula using the -3dB lower frequency required. (F_L is the lower frequency required)

$$C_{IN} \approx \frac{1}{2 \pi R_1 F_L} (F)$$

Note: This formula is true only if:

$$F_{CB} = \frac{1}{2 \pi (R_1 + R_2) C_B} (Hz)$$

is 5 times lower than F_L .

The following bill of material is an example of a differential amplifier with a gain of 2 and a -3dB lower cut-off frequency of about 80Hz.

Components:

Designator	Part Type
R1	20k / 1%
R2	20k / 1%
C_{in}	100nF
$C_b=C_s$	1 μ F

4.1.4 Daisy Chain Mechanical Data

Remarks

The daisy chain sample features two by two pin connections. The schematic above illustrates the way pins connect to each other. This sample is used to test continuity on your board. Your PCB needs to be designed the opposite way, so that pins that are unconnected in the daisy chain sample, are connected on your PCB. If you do this, by simply connecting a Ohmmeter between pin A1 and pin A3, the soldering process continuity can be tested.
